## **1. INTRODUCTION**

001. Volume 2 of the NISP focuses on interoperability standards and profiles in the near-term or a timeframe of 0 to 2 years into the future. This is the short-term step describing the state-of-the-art of NATO systems today and the framework for new systems actually under procurement or specification. For new systems, it describes the initial step towards the NII.

002. The Combined Communications Electronics Board (CCEB) nations will use NISP Volume 2 Chapter 4 tables to publish the interoperability standards for the CCEB under the provisions of the NATO-CCEB List of Understandings (LoU) detailed in Volume 1 Annex B. Sections 1, 2 and 3 of this volume are background information only for the CCEB. Chapter 4 are applicable to the non NATO CCEB Nations when taking part in NATO lead operations.

### **1.1. SCOPE**

003. The scope of this volume will include:

- Identifying the reference models, standards, profiles, and technologies that are relevant to the platform centric environment,
- Describing the near term Standards, profiles and technologies to support the initial step towards NII,
- Planning the transition of legacy systems.

## **2. REFERENCE MODELS: TRANSITION FROM PLATFORM CENTRIC TO SERVICE ORIENTED MODELS**

004. Information technology is undergoing a fundamental shift from platform-oriented computing to network-oriented computing. Platform-oriented computing emerged with the widespread proliferation of personal computers and the global business environment. These factors and related technologies have created the conditions for the emergence of network-oriented computing. This shift from platform to network is what enables the more flexible and more dynamic network-oriented operation. The shift from viewing partners as independent to viewing partners as part of a continuously adapting ecosystem fosters a rich information sharing environment.

005. This shift is most obvious in the explosive growth of the internet, intranets, and extranets. Internet users no doubt will recognize transmission control protocol/internet protocol (TCP/IP), hypertext transfer protocol (HTTP), hypertext markup language (HTML), Web browsers, search engines, and Java[1] Computing. These technologies, combined with high-volume, high-speed data access (enabled by the low-cost laser) and technologies for high-speed data networking (hubs and routers) have led to the emergence of network-oriented computing. Information "content" now can be created, distributed, and easily exploited across the extremely heterogeneous global computing environment. The "power" or "payoff" of network-enabled computing comes from information-intensive interactions between very large numbers of heterogeneous computational nodes in the network, where the network becomes the dynamic information grid established by interconnecting partners participating in a collaborative, coalition environment. At the structural level, network-enabled warfare requires an operational architecture to enable the common processes to be shared by all parties.

006. One of the major drivers for supporting net-enabled operations is Service-Oriented Architectures (SOA). SOA is enterprise architecture that leverages heterogeneity, and thus inherently platform-neutral. It is focused on the composition of Services into flexible processes and is more concerned with the Service interface and above (including composition metadata, security policy, and dynamic binding information), more so than what sits beneath the abstraction of the Service interface. SOA requires a different kind of platform, because runtime execution has different meanings within SOA. SOA enables business users and business process architects to compose Services into processes, and then manage and evolve those processes, in a declarative fashion. Runtime execution of such processes is therefore a metadata-centric operation of a different kind of platform -- a Service-oriented composite application platform.

007. Network-enabled operations are characterized by new concepts of speed of command and self-synchronization.

008. The most important SOA within an enterprise is the one that links all its systems. Existing platforms can be wrapped or extended in order to participate in a wider SOA environment.

[1]Registered Trademark of SUN Microsystems, INC.

NATO use of the NISP will provide a template for new systems development, as well as assist in defining the path for existing systems to migrate towards net-enabled operations.

## **3. STANDARDS**

### **3.1. INTRODUCTION**

009. This purpose of this chapter is to specify the NISP near term standards. Based on the NNEC FS, the document organises these standards into four service areas and included service categories:

- NNEC Application Services (NAS)
- COI Services (COI)
- NNEC Core Enterprise Services (CES)
  - Discovery (DIS)
  - Information Assurance (IAS)
  - Messaging (MES)
  - Enterprise Services Management (ESM)
  - Storage (STO)
  - Application (APP)
  - Mediation (MED)
  - Collaboration (COL)
  - User Assistant (UAS)
- Networking Information Infrastructure Services (NIIS)

010. This section describes the role and requirements of each service area, and presents all associated standards in tabular form. The tables refine each service area into one or more service categories, with service components mapping to one or more mandatory, emerging near term, fading or retired standards categories (see NISP vol. 1). A remarks column provides optional supplementary information on each standard plus CCEB-specific information. The NISP Rationale Document (RD) provides further explanation on why service and standards categories have been selected.

### **3.2. NNEC APPLICATION SERVICES**

SERVICE CATEGORY / CATEGORY	MANDATORY STANDARDS	EMERGING NEAR TERM	FADING	NTRM	Remarks
<b>NNEC APPLICATION SERVICES</b>					
Communication Services / Application Layer					

### **3.3. COI SERVICES**

011. COI services provide more specialized services in order to give the business more specific business benefits within a "domain" or "area of interest".

012. A COI is a collaborative group of users who have shared goals, interests, missions or business processes that result in information exchange and shared vocabulary.

### **3.4. NNEC CORE ENTERPRISE SERVICES**

013. Core services provide fundamental support to service based frameworks both in the form of infrastructure and enabler services, and in the form of COI independent general service building blocks.

014. Core services includes services that are either made available to all users by the infrastructure, or are mandatory to be provided by all users, by all providers or by all consumers. Core services also include specification of services of general interest that may be voluntarily exchanged by any parties on the network

015. Any service based framework, such as the Business Process Infrastructure Framework (BPIF), needs to provide a basic set of services that support and facilitate implementation and deployment of actual business services and processes. Such basic services are usually referred to as Core services.

016. Here we will provide an overview of such Core Services in a BPIF context in terms of the way such services are categorized. A few examples of core services in each category is also provided, but a complete set of well defined core services cannot be provided as it to a large extent will depend on the actual implementation of the BPIF.

017. Core services in a BPIF context are divided into two main categories according to their primary role in the implementation of business services and processes.

#### **3.4.1. Basic Infrastructure Services**

018. The first main category of core services, here referred to as Basic Infrastructure Services (BIS), are used to support the infrastructure (BPIF) that support deployment, operation and management of business processes. BIS is further divided into three subcategories according to three of the main aspects of a BPIF.

- Service Selection BIS are concerned with the basic mechanisms for discovery and visibility of services. Typically this encompasses basic service directories with support for syntactic description and lookup of services.

- Management and operation BIS are concerned with various types of management and operation of services and infrastructure. There are at least four subcategories.
  - BIS handling policies, including required security level, conditions for service delivery, availability, quality of service undertakings etc.
  - Security BIS include basic functions for managing information security, and a typical example is a service that keeps track of role and person oriented authorization, distribution of keys, handling of certificates etc.
  - Service Management BIS handle life cycle management of other services, including for example monitoring and configuration.
  - Resource Management BIS are used to manage infrastructure resources and will be highly dependent on infrastructure implementation. A typical example is resource management in a Grid.
  - Network Management BIS are concerned with networking and communication aspects of the infrastructure, and involve for example router configuration.
- Process Composition BIS are concerned with support for business processes.

### **3.4.2. Business Service Enablers**

019. The second of the main core service categories is Business Service Enablers (BSE). While BIS services are concerned with the BPIF infrastructure per se, they are not used a foundation for implementation of business services. This is instead the role of BSE, which provide basic functionality that is shared by many business services independently of Community of Interest (COI).

020. BSE are divided into three main subcategories based on the types of functionality they offer.

- Collaboration BSE support basic exchange of data between services. Examples include message passing (uni- and multicast, email, etc.), distributed file sharing, publication (web pages etc.), and data format conversion.
- Synchronization BSE support synchronization of service and process interaction, and includes for example time services, and event notification.
- Common Information Services (CIS) is the third and last subcategory of BSE. CIS provide COI-independent support for access to general information like maps, glossaries, standards, and document registries.

021. Note: Not all functions in this category are necessarily service oriented in a SOA sense.

They are nevertheless important for a network-oriented capability.

### **3.4.3. List of Standards**

<b>SERVICE CATEGORY / CATEGORY</b>	<b>MANDATORY STANDARDS</b>	<b>EMERGING NEAR TERM</b>	<b>FADING</b>	<b>NTRM</b>	<b>Remarks</b>

## **4. INTEROPERABILITY PROFILES**

### **4.1. MINIMUM INTEROPERABILITY PROFILE**

022. NATO, through its interoperability directive, has recognised that widespread interoperability is a key component in achieving effective and efficient operations. In many of the operations world-wide in which NATO nations are engaged, they participate together with a wide variety of other organisations on the ground. Such organisations include coalition partners from non-NATO nations, Non-Governmental Organisation (NGOs - e.g. Aid Agencies) and industrial partners. It is clear that the overall military and humanitarian objectives of an operation could usefully be supported if a basic level of system interoperability existed to enhanced the exchange of information.

023. To support the goal of widespread interoperability this section defines a minimum profile of services and standards that are sufficient to provide a useful level of interoperability. This profile uses only those services and standards that are already part of the NISP, however it presents them as a simple and easy to follow, yet comprehensive protocol and service stack.

#### **4.1.1. Architectural Assumptions**

024. This document assumes that all participants are using IP v4 packet-switched, routed networks (at least at the boundaries to their networks) and that interoperability will be supported through tightly controlled boundaries between component networks and systems; these may be connected directly or via a third-party WAN (see Figure 4.1 below). A limited set of services will be supported at the boundary, these requiring server-to-server interactions only. Each nation/organisation will be responsible for the security of information exchanged.

**Figure 4.1. NATO to National Connectivity**

025. Users will attach and authenticate to their local system/network. Information will only be shared using the limited set of services provided. It is also assumed that the information to be exchanged will predominantly be unclassified.

### **4.1.2. Shared Services**

026. The complete set of shared services will be a combination of the user-level services supported across the boundary and the infrastructure services necessary to deliver them. The user-level services that realistically can be shared are:

- Voice
- Mail
- FAX
- C2 information
- E-mail with attachments
- Web publishing/access
- News (Usenet)
- File transfer
- VTC
- Instant Messaging

027. To implement these services in a network enabled environment, the following must also be defined:

- NNEC Application Services
- COI Services
- NNEC Core Enterprise Services
- Network and Information Infrastructure Services

### **4.1.3. Minimum Architecture**

028. The following table defines the service areas, classes and standards that make up the minimum architecture. They represent a subset of the NISP.

Service Area	Class	Mandatory Standard	Comments
NNEC Application Services			
COI Services			
NNEC Core Enterprise Services			
	Messaging	SMTP (RFC 1870:1995, 2821:2001)	
	Application	FTP (IETF STD 9, RFC 959:1985 updated by 2228:1997, 2640:1999, 2773:2000)	
		HTTP v1.1 (RFC 2616:1999 updated by 2817:2000), URL (RFC 1738:1994 updated by 1808:1995, 2368:1998, 2396:1998, 2732:1999), URI (RFC 2396:1998 updated by 2732:1999)	
		Network News Transfer Protocol NNTP (RFC 977:1986)	
		MPEG-1 (ISO 11172:1993)	
		MPEG-2 (ISO 13818:2000)

Service Area	Class	Mandatory Standard	Comments
		792:1981, 894:1984, 919:1984, 922:1984, 1112:1989 updated by RFC 950:1985, 2474:1998, 3168:2001, 3260:2002, 3376:2002)	addresses must be valid public addresses (i.e. no private addresses to be routed across boundary)
		Border Gateway Protocol (BGP4) (RFC 1771:1995)	

**Table 4.1. NISP Lite**

## **4.2. X-TMS-SMTP PROFILE**

029. The following table defines military header fields to be used for SMTP messages that are gatewayed across military mail environment boundaries.

030. It specifies "X-messages" based upon RFC 2821, section "3.8.1 Header Field in Gatewaying". The profile specifies for each header field the name and possible values of the body.

031. The abbreviation TMS means Tactical Messaging System. The first column indicates an indication of the message property that will actually be represented by a X-TMS-SMTP field. The second and third columns specify the field names and the allowed values of the field bodies. All SMTP field values must be in uppercase

TMS message property	Field name	Field body
Subject	Subject	The Subject is a normal message property, no additional mapping is required.
Handling Name	X-TMS-HANDLING	Handling Name(s):  <ul style="list-style-type: none"> <li>• NO HANDLING</li> <li>• EYES ONLY</li> </ul>
Classification Group + Detail	X-TMS-CLASSIFICATION	The field value will be the combination of Classification Group Displayname + Classification Detail in uppercase.  Example: NATO SECRET

TMS message property	Field name	Field body
TMSStatus	X-TMS-STATUS	<ul style="list-style-type: none"> <li>• NEW MESSAGE</li> <li>• UNTREATED</li> <li>• IN PROCESS</li> <li>• HANDLED</li> </ul>
Mission	X-TMS-MISSIONTYPE	Type of the mission. Typical values: <ul style="list-style-type: none"> <li>• OPERATION</li> <li>• EXERCISE</li> <li>• PROJECT</li> </ul>
	X-TMS-MISSIONTITLE	Name of the Mission
	X-TMS-MISSIONDETAILS	Details of the mission. Typical values: <ul style="list-style-type: none"> <li>• UMPIRE</li> <li>• DISTAFF</li> <li>• CONTROL</li> <li>• NO MISSION DETAILS (default)</li> </ul> Note: This field is only used when the Mission type is set to EXERCISE.
Play	X-TMS-PLAY	This field contains either: PLAY or NO PLAY Note: This field is only used when the Mission type is set to EXERCISE.

TMS message property	Field name	Field body
UserDTG	X-TMS-USERDTG	The UserDTG element contains the DTG-formatted value entered by the user on the TMS Client or automatically set by the system (TMS).
Destinations	TO: (message data)	This is the complete list of action destinations, the SMTP session RCPT TO will dictate for which recipients the system must deliver the message to.  Syntax according to RFC 2822.
	CC: (message data)	This is the complete list of info destinations, the SMTP session RCPT TO will dictate for which recipients the system must deliver the message to.  Syntax according to RFC 2822.
SICs	X-TMS-SICS	List of SIC elements (separated by semicolon) selected by the user as applicable to the current message.
Precedences	X-TMS-ACTIONPRECEDENCE	Possible values:  <ul style="list-style-type: none"> <li>• FLASH</li> <li>• PRIORITY</li> <li>• IMMEDIATE</li> <li>• ROUTINE</li> </ul>
	X-TMS-INFOPRECEDENCE	Possible values:  <ul style="list-style-type: none"> <li>• FLASH</li> <li>• PRIORITY</li> <li>• IMMEDIATE</li> <li>• ROUTINE</li> </ul>

TMS message property	Field name	Field body
Related MessageID	X-TMS-RELATEDMESSAGEID	Used to relate TMS-, SMTP- and DSN messages

**Table 4.2. X-TMS-SMTP Profile**

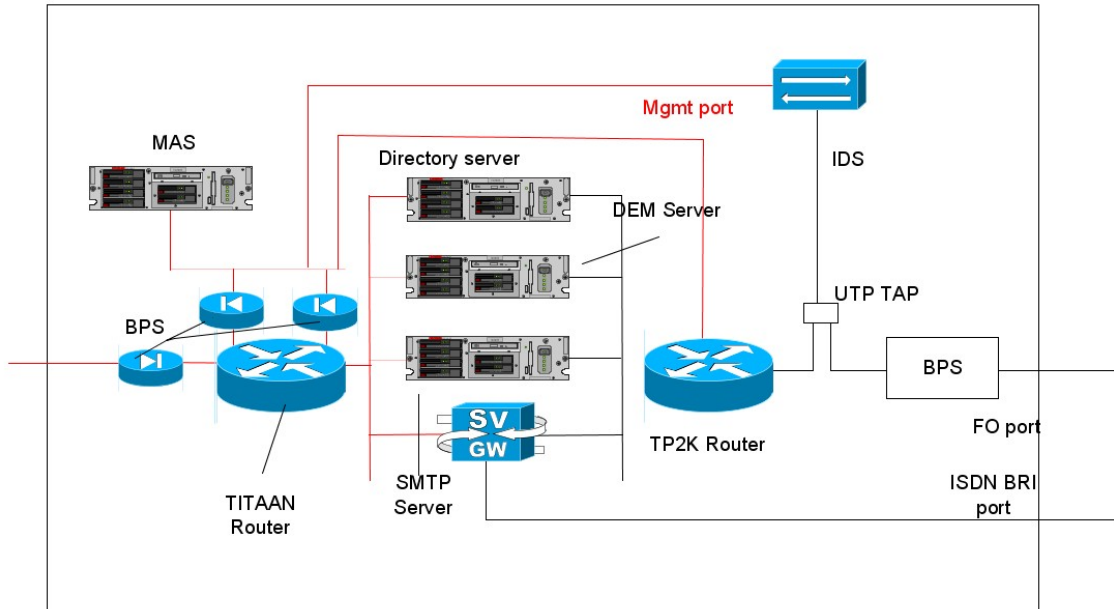

### **4.3. TACOMS POST-2000 PROFILE**

032. The following table defines the network and application interface, being used between participating nations within the NRF. It contains three different time periods (short, middle and long term), based on the modifications, based on the actual implementation and the foreseen updates within the 3 and 8 years cycle. This update cycle is in line with the cycle of the NISP.

033. These technical statements have to be extended by necessary operational regulations (e.g. necessary mapping profile for IP addresses).

034. The following Figure 4.2 describes visually this interface description, both for the network and the application part.

**Figure 4.2. Generic TACOMS Post-2000 Profile**

Protocol Layer	
Application	VoIP: ITU-T H.225, H.245, H.323 v5 Numbering Plan: Based upon TACOMS template as defined in STANAG 4643, Annex A
	VoIP: H.323v5-ISDN GW:
	MIP GW: MIP Block 2, C2IEDM 6.1.5e, Data Exchange Mechanism (mandatory), Message Exchange Mechanism (optional)
	SMTP GW: RFC 1870:1995, 2821:2001
Transport	TCP: RFC 793
	UDP: RFC 768
	RTP, RTCP: RFC 3550:2001
Network	IPv4: FC 791, 792, 2131
	Routing: static

<b>Protocol Layer</b>	
	IP-Addressing and Naming: Plan based upon TACOMS template as defined in STANAG 4644 Annex A
Data Link	IEEE 802.3
Physical	100BASE-FX, SC FO: ISO 9324-3

**Table 4.3. NRF Profile**

## **A. TECHNOLOGIES**

035. This annex describes the technologies that are projected to be available today or in the near term period which will enable the transformation towards the NII.

### **A.1. DATA STRATEGY**

#### **A.1.1. Data Management Strategy**

036. The ability to share information is a key factor for military success. NATO and National Information Systems have to provide the means for information exchange in any mission. The basic resource for all information systems is data, which, through the right interpretation, becomes information. As the value and cost of data increases, it becomes important that this critical resource be managed in a manner similar to other important resources. NATO Data Management will provide NATO-wide data standards and procedures for C3 requirements. The scope of NATO Data Management for C3 Systems Interoperability focuses on data architecture and data administration, and embraces the planning, organization and control of metadata, which delivers basic rules and standardized data elements (including definitions) to NATO bodies, agencies, common funded projects and is offered to national projects and programs.

037. The DMSWG is the multi-national working group in NATO, responsible to the Information Systems Sub-Committee for the development and maintenance of the NATO Data Management Policy, together with:

- Providing guidance on the coherent implementation of data management and administration across NATO,
- Establishing and operating data administration for the provision of Standard Data Elements (SDEs),
- Developing and maintaining a "NATO Data Administration Repository", which will include for example IER Registry and XML Registry functionalities, to support the provision of relevant data for information requirements.

038. The DMSWG mission is to manage the metadata of all information identified, required and authorized by NATO Tasking Authorities to support their information requirements. In particular, regarding discovery metadata, the DMSWG provides a NATO Metadata Directive and a Discovery Metadata Specification (DMS). The DMSWG mission is to manage the metadata of all information identified, required and authorized by NATO Tasking Authorities to support their information requirements. In particular, regarding discovery metadata, the DMSWG provides a NATO Metadata Directive and a Discovery Metadata Specification (DMS).

### **A.1.2. JC3IEDM**

039. The JC3IEDM is a merger of both the LC2IEDM (Land C2 IEDM, developed by the Multilateral Interoperability Programme (MIP)) and the NATO Reference Data Model, which was developed by a predecessor of the DMSWG. The JC3IEDM is published under cover of STANAG 5525.

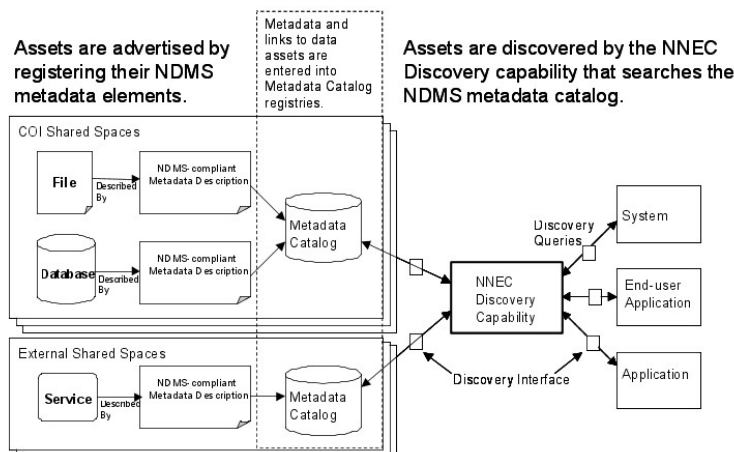

040. Since DMSWG is responsible for Data Administration not only for the JC3IEDM but also for any other Standard Information Exchange Mechanisms (Adat-P3 messages, Tactical Data Links, XML technologies, etc.) within NATO, it will also register and manage both the Standard Data Elements and the Information Exchange Requirements (IER) used in the development process of any of those mechanisms. DMSWG will as well publish Directive and Guidance documents for Data Administration in NATO.

041. As main tools for the Data Administration process, DMSWG has been tasked to develop and maintain both the NATO Metadata Registry and the NATO XML Registry. The objective is to implement them both with COTS products, if possible as a single system called NATO Metadata Repository, which would integrate both functionalities. Nowadays, the NATO IRDS (Information Resource Dictionary System) is a web-enabled tool that contains NATO Standard Data Elements in the form of a data model, but will in time need to be extended to meet selected requirements of the NATO Metadata Registry, thus becoming part of it. A version of the NATO XML Registry is currently posted under the DoD XML Registry.

### **A.1.3. NATO Discovery Metadata Specification (NDMS)**

042. The NDMS defines discovery metadata elements for resources posted to NATO shared spaces. "Discovery" is the ability to locate data assets through a consistent and flexible search method. The NDMS specifies a set of information fields that are to be used to describe any data or service asset that is made known to NATO, and it serves as a reference for developers, system architects, and engineers by identifying a minimum set of metadata elements in support of Discovery Services. Whilst discovery of data assets is the primary use of the NDMS it is also important to note that widespread use of the metadata elements will also improve documents record management in general. The NDMS will be employed consistently throughout the organization but it is not intended or necessary for it to displace other specifications that offer different semantics.

043. To support data asset discovery, NATO has developed the NDMS as the common set of descriptive metadata elements that are to be associated with each data asset that is made visible to the enterprise discovery capability. Metadata is often defined as being "data that describes and defines other data". Data assets available in the enterprise must be described with metadata, using the elements defined in this document to permit discovery through the enterprise discovery capability. The NDMS defines a minimum set of elements that must be used to describe data assets made visible to the enterprise. Users and system agents acting on their behalf that search the enterprise will discover data assets that have been tagged and entered into catalogues or repositories that respond to search queries specified in terms of NDMS entries as depicted in the NDMS Usage Conceptual Diagram in Figure A.1.

**Figure A.1. NDMS Usage Conceptual Diagram**

044. The elements specified in the NDMS are designed to be platform, language, and implementation independent. This allows system developers to generate and retain discovery metadata using any implementation approaches, including using COTS products. As future enterprise discovery interface specifications are defined, programs should have the appropriate discovery metadata available for their data assets and will only be required to format this metadata in accordance with the interface specifications.

**A.1.4. Extensible -up Language (XML)**

045. The Extensible Modelling Language (XML) is a simple, very flexible text format, much like HTML, used to structure, store and to send information. XML was designed to describe data and to focus on what data is. XML is also playing an increasingly important role in the exchange of a wide variety of data on the Web and elsewhere.

046. Role of XML in the Web Services model is lies within communication. When one application talks to another to perform a web service, the application doing the talking must package the message it is sending in a format that is understandable by the listening application. XML is the format of the message content in this communication process.

047. The Extensible Mark-up Language tags provide information about a document's components. The Uniform Resource Identifiers contained in the XML tags expand the concept of Uniform Resource Locators (URLs) by adding IDs for objects, concepts and values that are not dependent on location.

## **A.2. INFORMATION MODELLING**

048. The ability to share information is a key factor for military success. As such, NATO and National Information Systems have to provide the means for information exchange in all mission types. The basic resource for all information systems is data, which, through the right interpretation, becomes information, and knowledge in turn. As NNEC is considered the core theme for C3 systems within NATO transformation, a fundamental requirement is to work in the most effective manner through semantic interoperability at the data level for NATO/national C3 systems. The expanding missions of NATO involve consultation based on the sharing of information. Alliance members and partners are engaged in collective decision-making, with each nation retaining sovereignty and responsibility for its own decisions and taking action only on the basis of unanimity. In this environment, it is critically important that the Alliance members and partners have access to all shared information at the same time and that both the consultation process and the decisions taken are adequately documented. Information modelling and information management initiatives must be formalized throughout the NATO Enterprise to leverage the collective assets of NATO and national systems in support of information operations.

049. Information management is the handling of information acquired by one or many disparate sources in a way that optimizes access by all who have a share in that information or a right to that information. Information modelling establishes a conceptual schema that defines how the managed elements in an information environment are represented as a common set of objects and relationships between them. This allows multiple parties to exchange management information about these managed elements. Additionally, it provides means to actively control and manage these elements. By using a common model of information, management software can be written once and work with many implementations of the common model without complex and costly conversion operations or loss of information.

050. Appropriate Information management will enable:

- Awareness -- Products identified by metadata (keywords) and cataloged with a common schema providing a simple yet integrated query search for the right information (product);
- Access -- with information tags to define privileges; and,
- Delivery -- Assured delivery of the information product over the right network and to the right location.

051. This integrated approach to information modelling leverages the concepts of Net Centricity throughout all information resource providers and consumers in a coalition operation.

Key components of this strategy include a dissemination capability, with associated management services, that directs end-to-end information flows throughout the NII in accordance with command policy. The NISP will contribute to the core technical model for systems designers to develop new platforms capable of the intensive compilation, cataloguing, caching, distribution, and retrieval of data necessary to provide the life cycle information management and necessary information sharing across NATO members.

## **A.3. NETWORK INFRASTRUCTURE**

### **A.3.1. Background**

052. With the NATO Network Enabled Capability Feasibility Study (NNEC FS) a new concept of ensuring service interoperability was introduced that complements and reuses the architectural views. This concept dubbed the Interoperability Performance Parameters (IPP), inspired by the US developed concept of Key Performance Parameters (KPP), forces the system architects and designers to specify a wider context of their capabilities sufficient to allow secure service interoperability in a Federation of Systems (FOS). The interfaces at which interoperability between separate infrastructure capabilities is to be managed are called the Service Inter Operability Points (SIOP).

053. The principle is that an individual capability needs to work seamlessly with and within a FOS. The infrastructure services in a FOS and the international interoperability interfaces are described in the context of the total C4ISR systems architecture, often referred to as the Overarching Architecture (OAA).

054. This section describes the NATO General-Purpose Segment Communication System (NGCS) Reference Architecture (RA). NGCS is part of the NII, representing the NATO owned capability. It provides the communication services and associated management and security services. Also it describes the timeframe for NGCS up to 2014, first implementations are in progress.

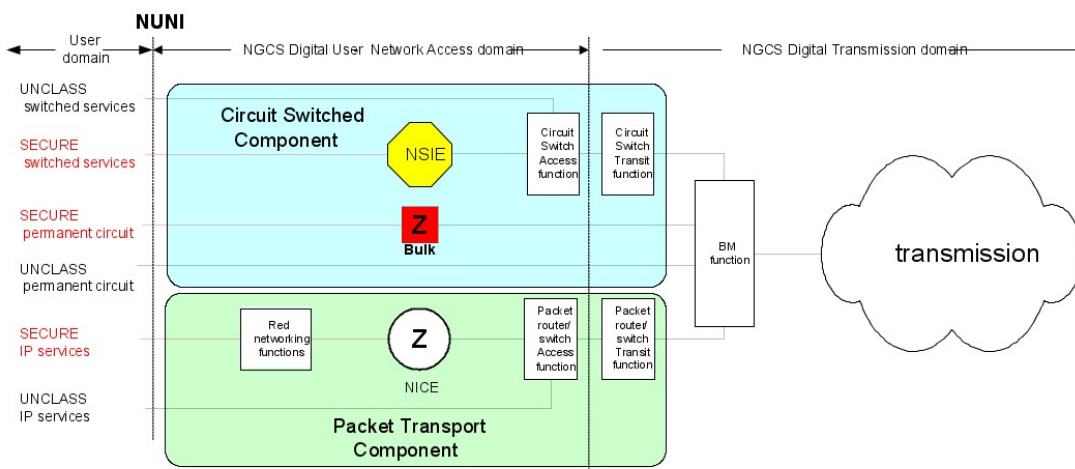

055. The major change to classical network infrastructures is the coherence and interoperability of infrastructure capabilities brought by different coalition partners that needs to be achieved. In the NNEC FS the concept of a Maturity Model [1] was introduced to describe, qualify and quantify the different levels of infrastructure capability. Increasing levels of maturity are characterised by enhanced sets of services, performances, and support, including advances in the associated Doctrine, Organisation, Training, Materials, Personnel, Leadership, Facilities (DOTMLPF) spectrum.

056. Interoperability of separate infrastructure capabilities is managed by the earlier mentioned concept of IPP. The IPP allows a more comprehensive description and specification of those parameters that are essential for providing scalable end-to-end services over combined infrastructure capabilities.

### **A.3.2. NGCS 2007 Target Architecture**

[1]Capability Maturity Model (CMM)

057. A reference model of the baseline network infrastructure for NGCS RA is depicted in Figure A.2. This architecture is described in the NGCS RA ed1. At the time of writing the NSIE and the NATO IP Cryptographic Equipment / Secure Access Router(NICE/SAR) had not been fielded, but the implementation projects were in progress. The BMF had been fielded.

**Figure A.2. NGCS Digital User-Network Access Reference Configuration**

### **A.3.3. Communications & Networking**

#### **A.3.3.1. Internet Protocol Version 4 (IPv4)**

058. Internet Protocol Version 4 (IPv4) is currently the dominant network layer protocol use in the communication between networked devices. IPv4 is a data-oriented protocol to be used on a packet switched inter-network (e.g., Ethernet). It is a best effort protocol in that it doesn't guarantee delivery. It doesn't make any guarantees on the correctness of the data; it may result in duplicated packets and/or packets out-of-order. All of these things are addressed by an upper layer protocol (e.g. UDP).

## A.3.3.2. Wireless Area Network (WAN)

### A.3.3.2.1. IEEE 802.11 (WiFi)

059. Many are familiar with 802.11, known as WiFi, as a short-range wireless networking protocol for home and office connections. 802.11 represent a family of wireless standards. The 802.11 series has been developed by the IEEE over the past 9 years as part of the range of communications protocols under the 802 standards series.

060. Each family member is identified by a letter suffix to the series name. Currently these letters run from "a" to "y", although there is the original 802.11 wireless standard as well. Note that there is no "l" or "x" standard. Some family members represent amendments (a, b, g, i) to the original standard, whereas some represents enhancements or extensions (c-f, h-j, n).

061. The 802.11 family of protocols share two common frequency bands, the so-called Industrial, Scientific and Medical (ISM) bands. At 2.4GHz and 5GHz, these frequencies are deregulated such that any devices complying with the Radio communications Agencies ISM conditions can operate without a radio licence. The retiring standards in this family are as follows:

062. **802.11:** The original wireless standard. Developed in 1997, it had a 2 Mbps maximum air interface rate. Two versions of 802.11 were available, a frequency hopping spread spectrum (FHSS) version and a direct sequence spread spectrum (DSSS) version, both in the 2.4GHz part of the spectrum. The standard suffered limited success and poor interoperability. **Status:** Largely supplanted by 802.11g.

063. **802.11a:** Until recently, this was the youngest member of the family, and the fastest. Operating in the far less congested 5GHz part of the RF spectrum, 11a offers headline data rates of 54Mbps per second, although in practical application the most users will see is around 20Mbps shared. **Status:** Mature low cost products available today and are shipped in volume.

064. **802.11b:** Not only the most successful member of the family, but also the most successful wireless available, 11b has driven wireless uptake. 11b took the basic DSSS mode of 802.11 and enhanced it with additional data rates up to 11Mbps, although most users in practice will see only around a fifth of this. However, cheap adapter cards and the potential for untethered network access has driven adoption to the point where it is expected more than 20 million 802.11b network cards will be shipped in 2003. **Status:** Mature low cost products available today and are shipped in volume.

065. **802.11c:** This provides mechanisms to bridge wireless LANs together to form a single network. Using the 802.11c standard between multiple access points running across a conventional wired network, multiple access points can coordinate their operation allowing members attached to different access points to exchange data. **Status:** complete and incorporated into available access point products.

066. **802.11d:** Different countries and regions have different conditions of using the ISM frequency bands. For example, wireless devices are permitted to operate at up to 1W transmission power. However, in the end, the maximum transmission power is a comparatively mea-

gre 100mW, thus significantly restricting the range and performance of wireless LANs. The 11d standard was drafted to ensure products were produced that conformed to the local license conditions in each country and region. Primarily effects countries with regulatory standards that are outside of those used by the U.S. **Status:** Standard ratified in 2001.

067. **802.11e:** Whilst the current 802.11 standards family can support voice and video communications, the quality of these exchanges rapidly deteriorates if the network is being heavily used. 802.11e introduces the concept of prioritisation to allow time sensitive information like voice and video data to be sent to users before other data, such as emails and web pages. This will significantly improve the ability of 802.11a, b and g networks to deliver voice and video services, and as proposed will be compatible with existing 802.11 standards and products. **Status:** Ratified in 2005. New products expected mid-2007. Firmware upgrades will be available for existing products.

068. **802.11f:** When developing the 802.11 standards, some features were purposefully omitted from the standard to promote differentiation between products. Inter-access point roaming was one such feature that allows end user devices to talk to different access points as they moved physically through a network. However it was soon realized that not standardizing this meant potential interoperability problems between different vendors' equipment; thus the 802.11f standard has been developed to facilitate an interoperable access point roaming capability. **Status:** Few products supporting 11f available; security issues and dismissal by vendors has lead to the standard being withdrawn.

069. **802.11g:** The latest member of the family to see products appearing, although the standard is still to be ratified. 11g introduce the same modulation and air interface schemes as 11a, but in the 2.4GHz ISM band. Thus 2.4GHz devices can now enjoy the same data rates (up to 54Mbps, although 20Mbps is more realistic) as 802.11a, although the available number of channels is restricted. Backwards compatible with 11b, there is some concern about the achievable data rates in mixed-mode 11b and 11g networks. **Status:** Standard ratified in 2003. Products are mature and will soon overtake 11b as the most popular standard within the family.

070. **802.11h:** Regulators have mandated that wireless devices operating in the 5GHz ISM band must be polite to one another, and to other users of the spectrum. It is interesting to note though that this has meant the network cards available are common to all countries and regions and it is the network card driver that manages the radio resources to comply with local licence conditions. This has resulted in many European users using US drivers for their wireless cards because of improved range.5GHz spectrum. This means they should detect other networks operating in the same frequencies and try to avoid them. 11h introduces Dynamic Frequency Selection to enable wireless devices to avoid already used frequencies automatically and Transmission Power Control to restrict the transmit power of devices to just that required to maintain the communications. **Status:** Ratified in 2004.

071. **802.11i:** The IEEE has developed stronger security mechanisms under the 802.11i banner. Based on the 802.1x, Port Based Security mechanisms and introducing the significantly more advanced and stronger (Advanced Encryption Standard) cryptographic algorithm, 11i should provide much greater levels of protection than the previous standard, WEP. **Status:** Ratified in 2004. Products are coming to market.

072. **802.11j**: Important for , because they have authorised a slightly different frequency for 802.11 (4.9-5.0 GHz). This standard brings to the Japanese authorised bands. **Status**: Ratified in 2004. Products are available in Japanese market.

Standard	Description	Status
IEEE 802.11	The original 1 Mbit/s and 2 Mbit/s, 2.4 GHz RF and IR standard	Approved 1997
IEEE 802.11a	54 Mbit/s, 5 GHz standard	Approved 1999
IEEE 802.11b	Enhancements to 802.11 to support 5.5 and 11 Mbit/s	Approved 1999
IEEE 802.11d	International (country-to-country) roaming extensions	Approved 2001
IEEE 802.11e	Enhancements: QoS, including packet bursting	Approved 2005
IEEE 802.11f	Inter-Access Point Protocol (IAPP)	Withdrawn 2006

**Table A.1. 802.11x Summary**

### **A.3.4. Construction of a robust IP-network infrastructure**

073. Operational relevant service availability should be one of the main design criteria and operational evaluation criteria for the NGCS. Despite the migration of users onto a single network and the introduction of significant additional complexity, e.g. QoS, the service availability has to be improved. Service availability and performance are exponents of infrastructure, organization, human aspects and others. The assessment of operational service readiness and performance is a structural activity required in the NGCS product life-cycle management. It should give input to transformational processes and for the development of Target Architectures (TA) that underpin infrastructure investment projects.

#### **A.3.4.1. NGCS Overview**

074. The NATO General Purpose Communications System (NGCS) has a Circuit Switched

Component (CSC) and a Packet Transport Component (PTC). The services offered are presented at the NGCS User Network Interface (NUNI). The NGCS user-network access domain incorporates functions for user access of circuit switched functions and packet transport functions. The circuit switched component provides on-demand switched access and also access to semi-permanent circuits. Both can be provided either in secure or non-secure modes. The packet transport component provides for both secure and non-secure IP access services.

075. A secure service offered by the network at the NUNI provides for interconnection within a single security domain. If telecommunication services are required for a second security domain, this is implemented by installation of another cryptographic device - e.g. NATO Secure ISDN Equipment (NSIE) offering bulk encryption or NATO IP Cryptographic Equipment (NICE) (with the associated RED networking functions). In order to provide greater throughput, more than one instance of this might exist for a single security domain.

076. In mid-term, a complete migration to a fully IP based network is planned for the NGCS.

### **A.3.4.2. Definition and implementation of a QoS architecture**

077. In the public standardization bodies, e.g. IETF, ITU, ETSI, ANSI, many initiatives are ongoing regarding the specification of a global QoS architecture in support of network convergence. Likewise many government organizations are doing the same.

078. The operation and control of QoS enabled IP-services requires many new Operation and Support Systems as well as a thorough reassessment of the management organization.

079. The complexity and the novelty of IP QoS warrant a step-by-step introduction. The entities affected by the introduction are:

- The end-user;
- The applications;
- The infrastructure;
- The OSS/BSS;
- The policies;
- The third party providers, e.g. SP, NDN;

080. The introduction should follow the developments in the commercial sector, and each successive introduction step in NATO should be done when the technology is stable and mature. Nevertheless NATO may want to implement additional functionality like additional CoS to implement MLPP, but this always be based on an underlying commercial standard based QoS architecture. Eventually the QoS architecture must take account of the requirements in military tactical radio networks and future QoS enabled MANETs. It is envisaged however

that commercial standards for wireless MANETs will be developed among others by the Zig-Bee Alliance

081. The model of spiral development should be applied. Each step is first tested in the laboratory (applications, infrastructure and OSS/BSS), evaluated against user requirements, operational issues, architectural principles, before it is gradually rolled out in the operational network.

082. Business cases for network convergence are becoming increasingly viable. As more and more services are uniquely available on IP and standardization for IP based service support is becoming mature, it becomes more cost effective to migrate an existing infrastructure based on TDM and IP bearers to a single IP-bearer service system. However, network convergence does not come for free. Following items and activities are required:

- Specification of a comprehensive set of Classes of Service (CoS) for the ultimate network, which can be initially collapsed to a basic set and further expanded with each implementation step.
- Definition of application mapping to telecommunications services (the CoS).
- Specification of CoS handling in the network
- NATO policy with the objective to have uniform QoS handling in the multinational network.
- Supporting management and control systems (NGOSS compliant) that need to be integrated in the total SLM complex.
- Proof of concept testing.

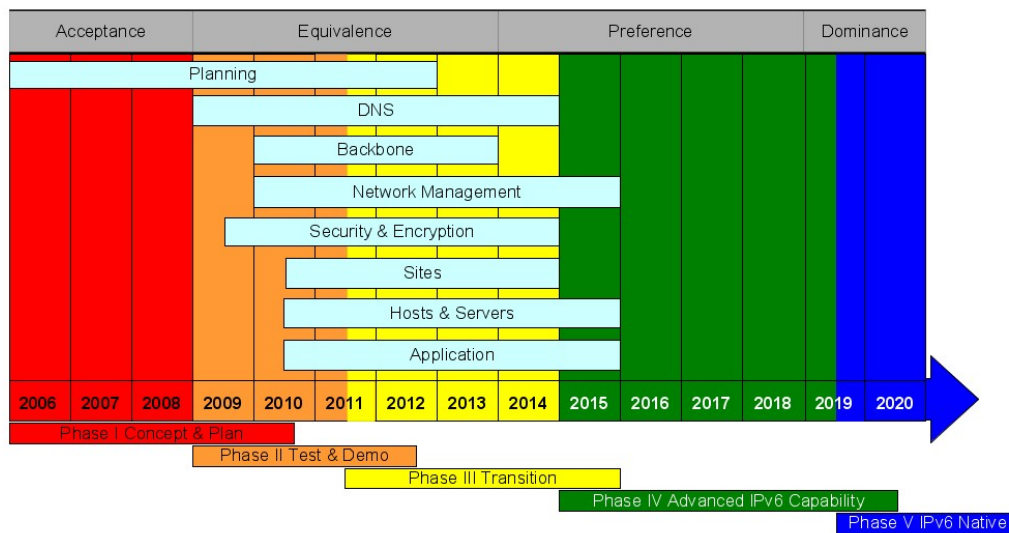

### **A.3.4.3. The migration of applications onto an IP-bearer**

083. All the applications that are often traditionally carried on the CSC, i.e. telephony, switched VTC, leased line (for real-time data, for bandwidth pipe) need to be adapted so that they can also perform on an IP-bearer. Most of the applications require an QoS enabled IP infrastructure. In addition the connection oriented application services require call signalling, DNS, directory (for the gatekeeper) and resource reservation functionality. This infrastructure should be provided as a common core functionality for all application services requiring it. Target architectures for VoIP (SVoIP and VoSIP) and VTCoIP therefore need to be coordinated. For interoperability purposes NATO needs to standardize the signalling at the respective Service Interoperability Points.

### **A.3.4.4. Transition to IPv6**

084. IPv6 is an enabler for establishing coalition wide connectivity in a network enabled NII. The transition strategy of the NATO CIS to IPv6 is described in [TN1088] [2] from which the

top-level roadmap is repeated here in Figure A.3.

**Figure A.3. Roadmap to IPv6**

**A.4. PLATFORM ORIENTED COMPUTING**

085. This section contains the description of the reference models, more specific the NCOE Component Model (NCM), associated with basic functional configurations. Although these Functional Configurations (FC) are not for future systems, they still describe the reality of today's system implementation. Ten baseline FCs have been identified which can each be extended with additional functionality. For a number of FCs a refinement has been made in terms of functionality provided.

**A.4.1. User Terminal/Device**

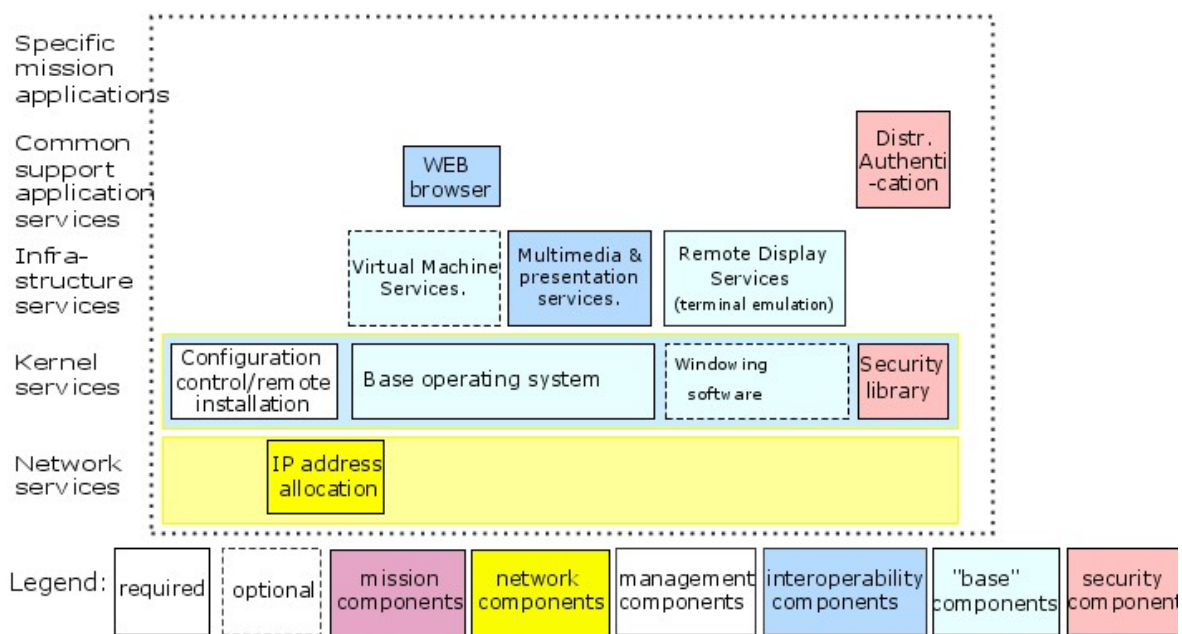

086. User Terminals/Devices are appropriate for a large community of NATO users that require light office applications such as email, office automation, browsing capability to view Intranet documents and possibly some specific business applications. The User Terminal is considered a light client station with an embedded operating system, a browser and a virtual

[2]Derived from Technical Note 1088: NATO IPv6 Transition Plan, Preliminary Version, NC3A, June 2006

machine. Devices can be PDAs, or WAP phones. Applications are downloaded from the internal Communications server or the Webportal. User Terminals/Devices are appropriate for a large community of NATO users that require light office applications such as email, office automation, browsing capability to view Intranet documents and possibly some specific business applications.

087. The following options can be provided when required:

- Multi-point Applications,
- DBMS Services,
- Distributed Applications like e.g. Workflow and Alert services.

**Figure A.4. Functional Components for User Terminal/Device**

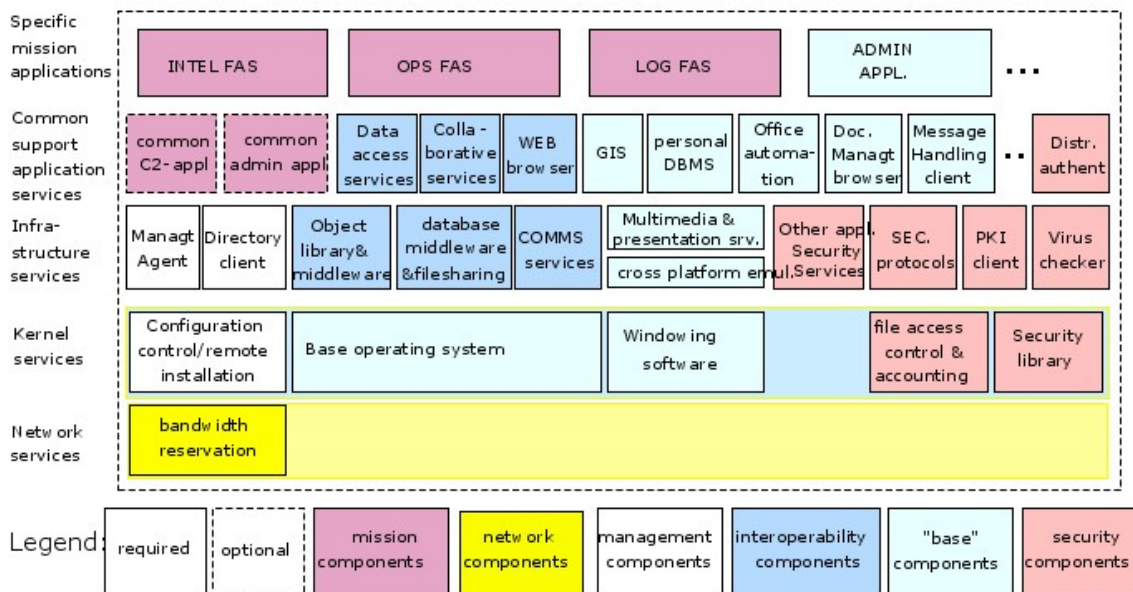

### **A.4.2. User Workstation**

088. User Workstations are appropriate for users that require heavy applications that are

stored locally to improve response times. This can be a MMHS Client Workstation, a GIS Workstation, a Data Provider Workstation or a laptop. They offer full Office Automation and Formal Military Messaging capabilities with optional functionality as required. Client Network Management Services are considered part of the Operating System. GIS and personal DBMS are optional services for data providers. Data consumers access GIS and data through their browser and data access services respectively. File encryption is an optional feature for user workstations, but very appropriate for mobile users, using laptops. The optional collaborative or multi-point tools are near real-time applications, comprising audio and video conferencing, briefings, real-time chat, white-boarding, and application sharing.

089. The following options are considered:

- Map Overlay and GIS Services,
- Multi-point Applications including VTC,
- Security Management such as PKI,
- Common Information Exchange,
- Distributed Applications like e.g. Workflow and Alert services.

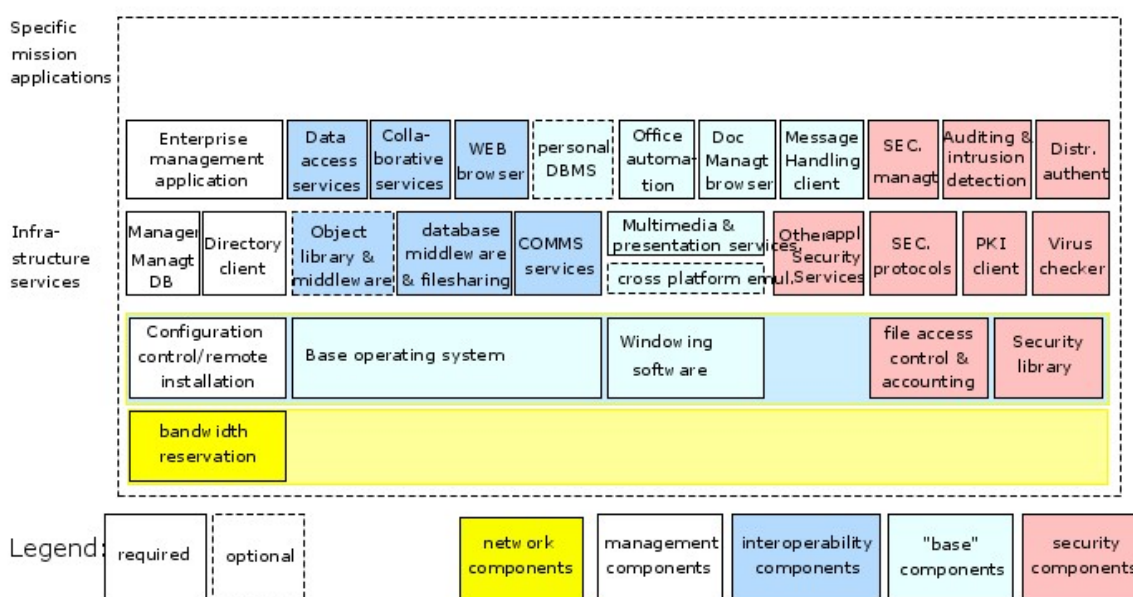

**Figure A.5. Functional Components for User Workstation**

090. A possible simplification of a User Workstation is an End User Device, which may be appropriate for a large community of NATO users that require light office applications such as e-mail, office automation, browsing capability to view Intranet documents and possibly some specific business applications.

### A.4.3. Administration Workstation

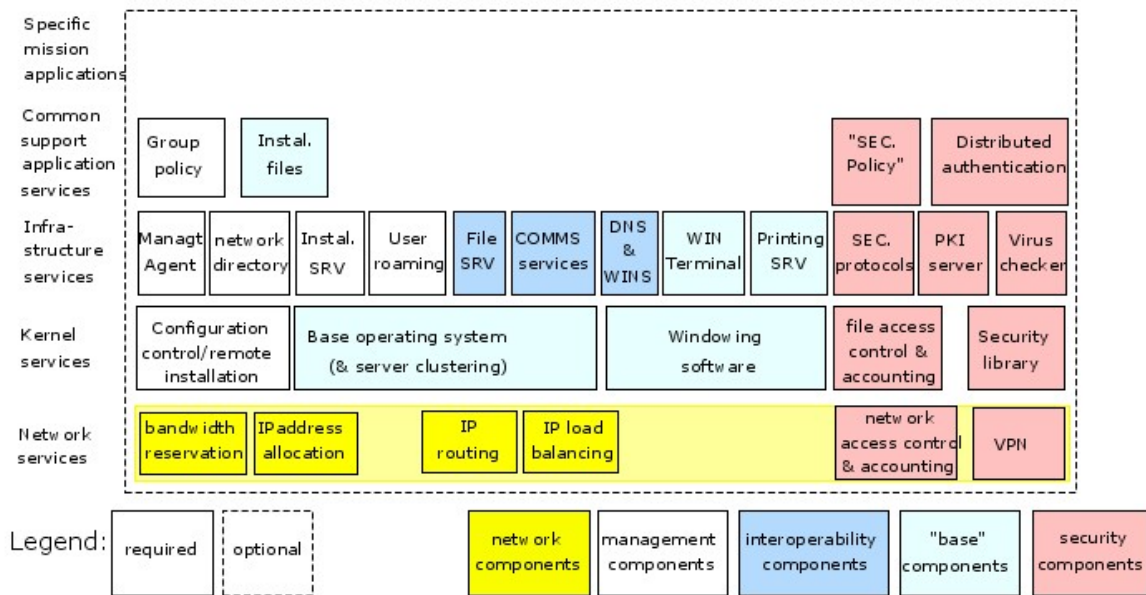

091. Administration Workstations are appropriate for system, network, and security administrators. In addition to the User Workstation functionality they offer system administration and full systems and network management services.

**Figure A.6. Functional Components for Administration Workstation**

### A.4.4. Network Server

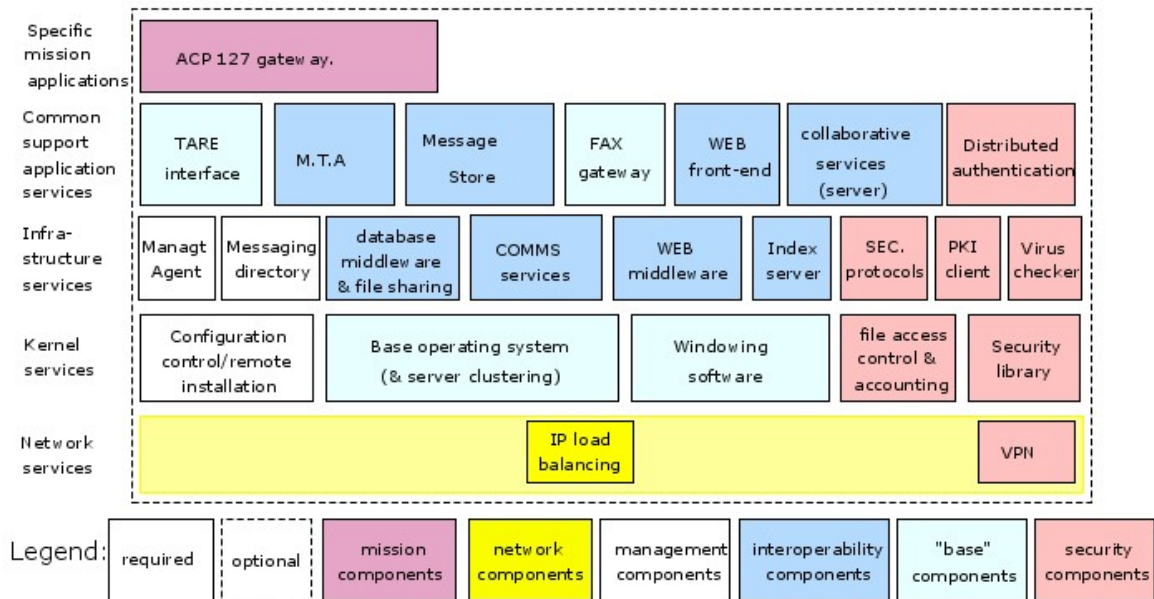

092. The Network Server is used for communication with the external WAN and for providing internal LAN services, such as downloading applications to user terminals. Within NATO a strategic choice for the Windows 2000 platform has been made for all network servers.

**Figure A.7. Functional Components for Network Server**

**A.4.5. Communications and Messaging Server**

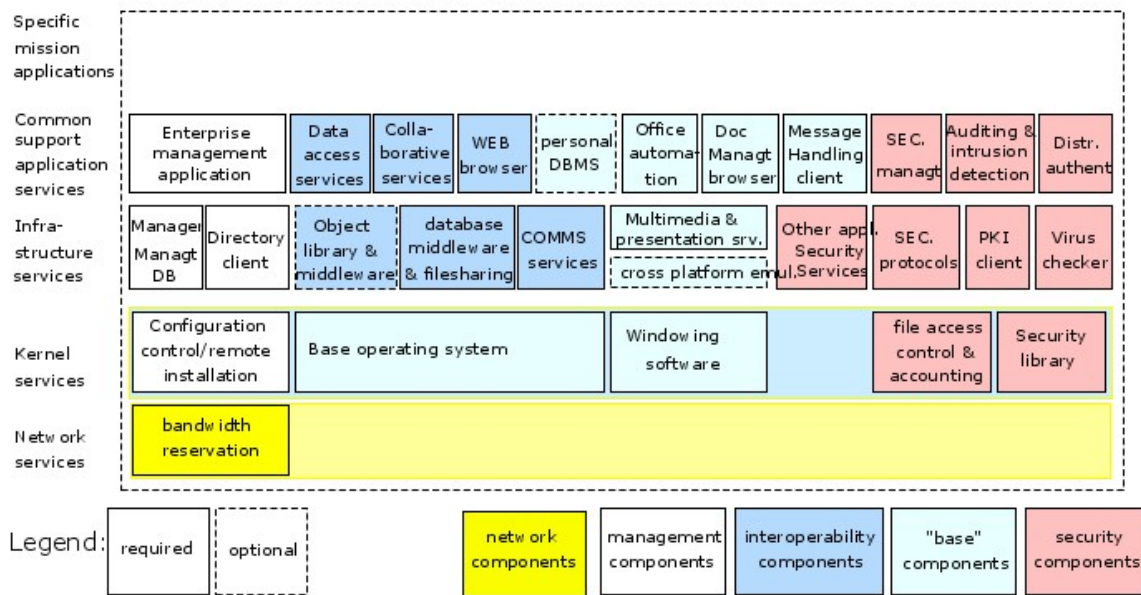

093. The communications and messaging server provides all formal and informal mail services and interface with ACP 127 networks.

**Figure A.8. Functional Components for Communications and Messaging Server**

**A.4.6. Document Management Server**

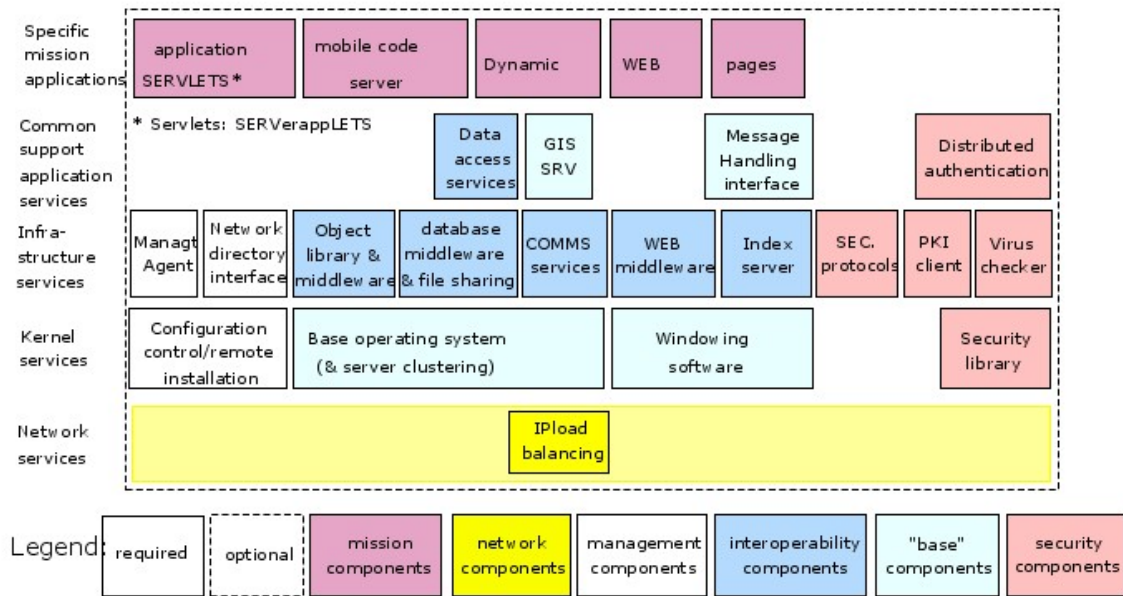

094. The document management server provides the document storage and retrieval engine and hosts workflow applications. Also collaborative tools are hosted on the document management server because they support the workflow applications.

**Figure A.9. Functional Components for Document Management Server**

### A.4.7. Web Portal/Application Server

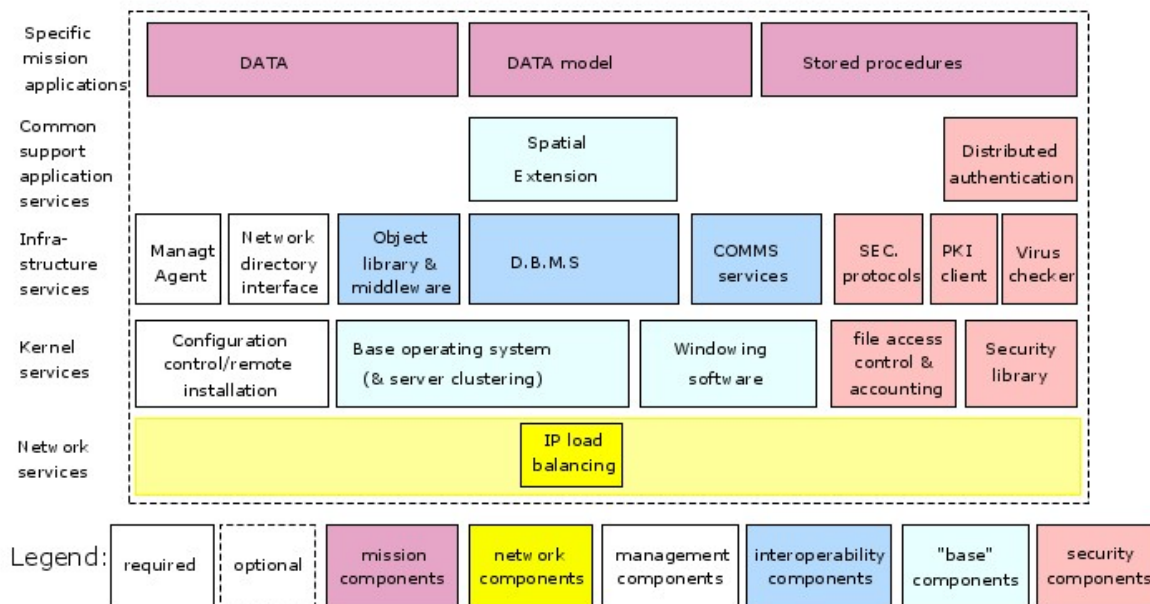

095. The web portal/application server provides the access to intranet and Internet services. It optionally contains GIS and MHS components to provide geographic mapping and messaging services.

**Figure A.10. Functional Components for Web Portal/Application Server**

**A.4.8. Database Application Server**

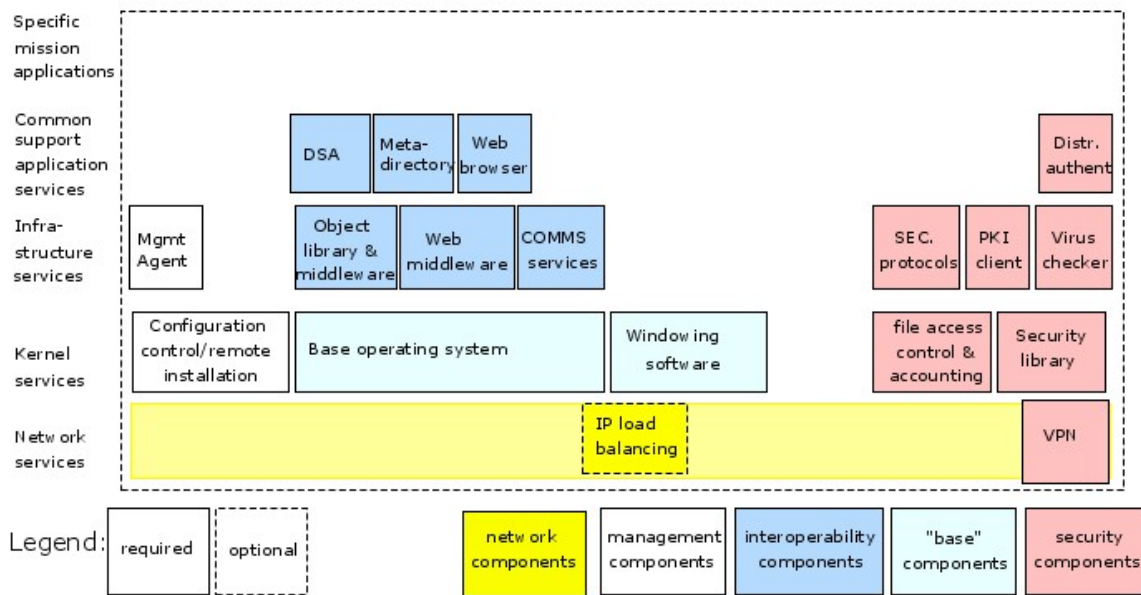

096. The database application server provides the access to local database services. It optionally contains spatial services to provide storage and retrieval of geographic maps.

**Figure A.11. Functional Components for Database Application Server**

### A.4.9. Directory Server

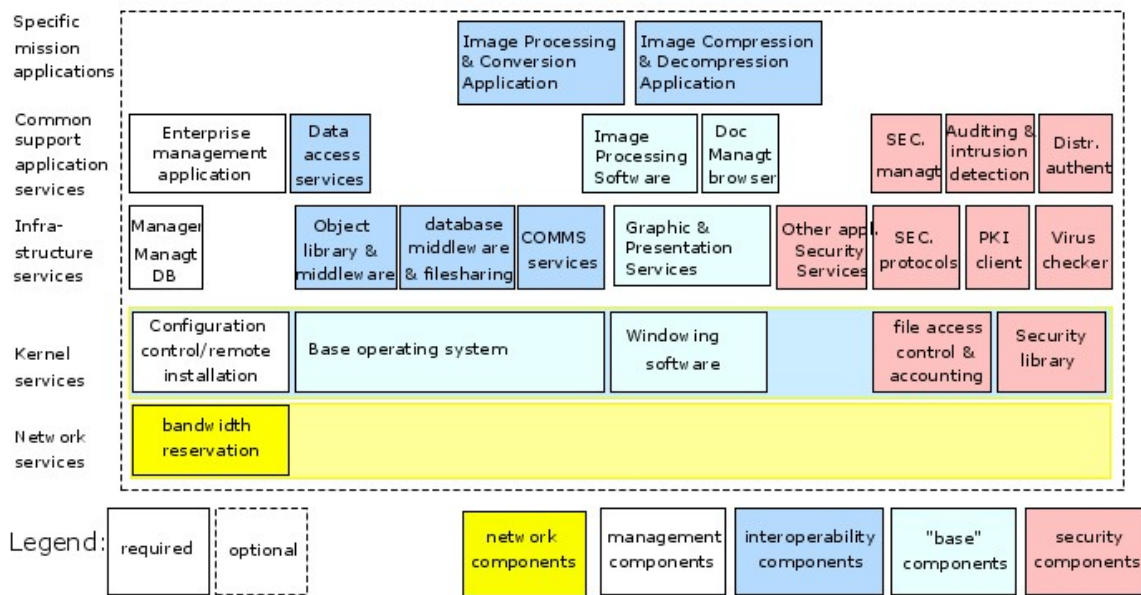

097. The directory server offers central information support for users/systems through the provision of standardised information contents in the form of objects, e.g. for the support of addressing within messaging systems and the storage of certificates/CRLs within PKI.

**Figure A.12. Functional Components for Directory Server**

**A.4.10. Imagery Server**

098. The imagery server offers data exchange interoperability between NATO reconnaissance and surveillance assets levels of interoperability. The main focus is on the imagery interfaces between airborne and surface-based elements and between the output of the surface-based elements and the rest of the imagery community.

**Figure A.13. Functional Components for Imagery Server**
